**F. Establishment and calculation of reference emissions**

**F.1. Establishment of reference emissions**

Electricity and fossil fuel are consumed for the process of producing lead acid batteries in tank formation facilities.

Reference emissions from electricity consumption are calculated by multiplying specific electricity consumption per unit of lead acid battery type $i$ ($SEC_{RE,i}$) [kWh/unit], production output of lead acid battery type $i$ [units/p], and CO₂ emission factor for electricity consumed [tCO₂/MWh].

Reference emissions from fuel consumption are calculated by multiplying specific net heat quantity required for fuel consumption per unit of lead acid battery type $i$ ($SNHQ_{RE,i}$) [MJ/unit], production output of lead acid battery type $i$ [units/period] and CO₂ emission factor for fuel which is determined as per a factory where a JCM project is implemented [tCO₂/GJ].

In this methodology, $SEC_{RE}$ is calculated with the equation specified, which is formulated in a conservative manner by excluding the electricity consumption by chiller and cooling tower to achieve net emission reductions while typical configuration of the equipment for producing lead acid batteries in tank formation facilities consists of the followings: formation tank, charging facility, chiller and cooling tower and other tank formation facilities such as washing facility and/or drying facility.

**F.2. Calculation of reference emissions**

$$RE_p = \sum_k [(EC_{RE,k,p} \times EF_{elec,k}) + (NHQ_{RE,k,p} \times EF_{fuel,k})]$$
\[
EC_{RE,k,p} = \sum_i (SEC_{RE,i,k} \times N_{i,k,p}) \times \frac{1}{1,000}
\]
\[
NHQ_{RE,k,p} = \sum_i (SNHQ_{RE,i,k} \times N_{i,k,p}) \times \frac{1}{1,000}
\]
\[
SEC_{RE,i,k} = 0.1338 \times AH_i + 0.1531
\]
\[
SNHQ_{RE,i,k} = 0.3282 \times AH_i + 0.9377
\]

Where

- \( RE_p \) Reference emissions during the period \( p \) [tCO\(_2\)/p]
- \( EC_{RE,k,p} \) Electricity consumption by tank formation facilities in the project factory \( k \) during the period \( p \) [MWh/p]
- \( EF_{elec,k} \) CO\(_2\) emission factor for electricity consumed in the project factory \( k \) [tCO\(_2\)/MWh]
- \( NHQ_{RE,k,p} \) Net heat quantity required for fuel consumption to produce lead acid battery by tank formation facilities in the project factory \( k \) during the period \( p \) [GJ/p]
- \( EF_{fuel,k} \) CO\(_2\) emission factor for fuel applicable to the project factory \( k \) [tCO\(_2\)/GJ]
- \( SEC_{RE,i,k} \) Specific electricity consumption per lead acid battery type \( i \) by the reference facilities in the project factory \( k \) [kWh/unit]
- \( SNHQ_{RE,i,k} \) Specific net heat quantity required for fuel consumption per lead acid battery type \( i \) by the reference facilities in the project factory \( k \) [MJ/unit]
- \( N_{i,k,p} \) Production output of lead acid battery type \( i \) in the project factory \( k \) during the period \( p \) [units/p]
- \( AH_i \) Capacity of lead acid battery type \( i \) [Ah/unit]
- \( i \) Identification number of the project lead acid battery type
- \( k \) Identification number of the project factory

**G. Calculation of project emissions**

\[
P_{Ep} = \sum_k (EC_{PJ,k,p} \times EF_{elec,k})
\]

Where

- \( P_{Ep} \) Project emissions during the period \( p \) [tCO\(_2\)/p]
- \( EC_{PJ,k,p} \) Electricity consumption by the container formation facilities including chillier and cooling tower in the project factory \( k \) during the period \( p \) [MWh/p]
Sectoral scope: 03

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description of data</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>$EF_{elec,k}$</td>
<td>CO₂ emission factor for electricity consumed in the project factory $k$ [tCO₂/MWh]</td>
<td>[Grid electricity] Ministry of Natural Resources and Environment (MONRE), Vietnamese DNA for CDM unless otherwise instructed by the Joint Committee.</td>
</tr>
<tr>
<td></td>
<td>Identification number of the project factory</td>
<td>[Captive electricity] For the option a) Specification of the captive power generation system in the project factory $k$ provided by the manufacturer ($\eta_{elec,CG,k} [%]$). CO₂ emission factor of the fossil fuel type used in the...</td>
</tr>
</tbody>
</table>
available from the source stated in this table at the time of validation

For captive electricity, it is determined based on the following options:

a) Calculated from its power generation efficiency in the project factory \( k \) (\( \eta_{elec,CG,k} [%] \)) obtained from manufacturer’s specification
The power generation efficiency based on lower heating value (LHV) of the captive power generation system from the manufacturer’s specification is applied;

\[
EF_{elec,k} = 3.6 \times \frac{100}{\eta_{elec,CG,k}} \times EF_{fuel,CG,k}
\]

b) Calculated from measured data
The power generation efficiency calculated from monitored data of the amount of fuel input for power generation (\( FC_{PJ,CG,k,p} \)) and the amount of electricity generated (\( EG_{PJ,CG,k,p} \)) in the project factory \( k \) during the monitoring period \( p \) is applied. The measurement is conducted with the monitoring equipment to which calibration certificate is issued by an entity accredited under national/international standards;

\[
EF_{elec,k} = FC_{PJ,CG,k,p} \times NCV_{fuel,CG,k} \times EF_{fuel,CG,k} \times \frac{1}{EG_{PJ,CG,k,p}}
\]

Where:

\( NCV_{fuel,CG,k} \): Net calorific value of fuel consumed by the captive power generation system in the project factory \( k \) [GJ/mass or volume]

| captive power generation system in the project factory \( k \) (\( EF_{fuel,CG,k} [tCO_2/GJ] \)) |
| For the option b) Generated and supplied electricity by the captive power generation system in the project factory \( k \) (\( EG_{PJ,CG,k,p} [MWh/p] \)). Fuel amount consumed by the captive power generation system in the project factory \( k \) (\( FC_{PJ,CG,k,p} [mass \ or \ volume/p] \)). Net calorific value (\( NCV_{fuel,CG,k} [GJ/mass \ or \ volume] \)) and CO\(_2\) emission factor (\( EF_{fuel,CG,k} [tCO_2/GJ] \)) of the fuel consumed by the captive power generation system in the project factory \( k \) in order of preference: 1) values provided by the fuel supplier; 2) measurement by the project participants; 3) regional or national default values; 4) IPCC default values provided in tables 1.2 and 1.4 of Ch.1 Vol.2 of 2006 IPCC Guidelines on National GHG Inventories. Lower value is applied. |

[Captive electricity with diesel fuel] CDM approved small scale methodology: AMS-I.A.
Note:
In case the captive electricity generation system meets all of the following conditions, the value in the following table may be applied to EF\(_{elec,k}\) depending on the consumed fuel type.

- The system is non-renewable generation system
- Electricity generation capacity of the system is less than or equal to 15 MW

<table>
<thead>
<tr>
<th>fuel type</th>
<th>Diesel fuel</th>
<th>Natural gas</th>
</tr>
</thead>
<tbody>
<tr>
<td>EF(_{elec,k})</td>
<td>0.8 (^*1)</td>
<td>0.46 (^*2)</td>
</tr>
</tbody>
</table>

*1 The most recent value at the time of validation is applied.
*2 The value is calculated with the equation in the option a) above. The lower value of default effective CO\(_2\) emission factor for natural gas (0.0543 tCO\(_2\)/GJ), and the most efficient value of default efficiency for off-grid gas turbine systems (42%) are applied.

\(\text{EF}_{fuel,k}\) CO\(_2\) emission factor for fuel applicable to the project factory \(k\) [tCO\(_2\)/GJ]

In case tank formation facilities exist in the project factory prior to the project implementation, the lowest CO\(_2\) emission factor of the fuel used by the facilities may be applied.

Otherwise, CO\(_2\) emission factor for Natural Gas is applied.

[Captive electricity with natural gas]
2006 IPCC Guidelines on National GHG Inventories for the source of EF of natural gas.
CDM Methodological tool "Determining the baseline efficiency of thermal or electric energy generation systems version02.0" for the default efficiency for off-grid power plants.

Country specific data or IPCC default value from “2006 IPCC Guidelines for National Greenhouse Gas Inventory”. Lower limit value of the default net calorific value is applied.
